BACHELOR THESIS

Development of Data Lake Core with Append-Only Storages and Query Polymorphism

AuthorNguyễn Gia Phong $Supervisor \\ \label{eq:Supervisor}$ Trần Giang Sơn, PhD

Declaration

I declare that I have composed this thesis in its entirety, as the result of my own work, unless explicitly indicated otherwise via referencing. The presented work has not been submitted for any previous application for a degree or professional qualification.

Lời Cam Đoan

Tôi xin cam đoan rằng tôi đã soạn toàn bộ luận án này, hoàn toàn từ kết quả công việc của chính bản thân tôi, trừ khi được chỉ rõ qua trích dẫn. Công việc được trình bày chưa bao giờ được nộp cho việc cấp học vị hay chứng chỉ trình độ chuyên môn nào trước đây.

1

Introduction

1.1 Motivation

Many researchers at University of Science and Technology of Hanoi (USTH) operate with data on a regular basis and often a dataset is studied by multiple researchers from different departments and points in time. Currently the data are organized manually, even on the laboratories' storages, which is prone to duplication and makes data discovery difficult.

A data lake shared among the university's researchers, professors and students will not only save resources but also improve productivity and promote interdisciplinary collaborations. With USTH's goal of growing to be an excellent research university in Việt Nam and in the region [1], building such data lake can be an essential task.

1.2 Background

A data lake is a massive repository of multiple types of data in their raw format at scale for a low cost [2]. The data's schema (structure) is defined on read to minimize data modeling and integration costs [2].

For the ease and efficiency of scaling, a microservice architecture could be a good choice. By arranging the data lake as a collection of loosely-coupled services, it becomes possible to scale individual services individually [3]. In this architecture, the *core* microservice is defined as the innermost component, which communicates directly with the storages. The core shall provide an application programming interface (API) for other components to upload, query and extract data.

Append-only storages only allow new data to be appended, whilst ensure the immutability of existing data. As immutable data are thread-safe, they reduce the complexity of the concurrency model, making it easier to comprehend and reason about [4]. This is particularly useful in a large distributed system with multiple moving parts.

In such storages, operations boil down to only two kinds: appending and reading. For the latter, sometimes the data are not wanted in their entirety, but filtered and accumulated. While data of different types usually requires different tools and libraries to query upon, the core API should be providing one single query language for all data types, plus their metadata. In this report, such usage is referred to as query polymorphism.

1.3 Objectives

I worked on this project as an intern for three months with other students in USTH ICTLab¹ to build a data lake to better manage the university's data. My work focused on the lake's core microservice, which abstracts underlying persistent layers and perform relevant metadata transformation and discovery. It should provide an internal interface to other components for data ingestion, (primitive) query and extraction, as well as carrying out tasks for enhancing the discoverability and usability of the aforementioned datasets.

1.4 Expected Outcomes

The intended deliverables of the three-month internship are listed as follows:

- Requirement analysis of the data lake core
- Data lake core's architecture and design
- Core API design and specification
- Implementation and integration with other components

2 Methodology

- 2.1 Requirement Analysis
- 2.2Architecture
- 2.3 Design
- **Technology Choices** 2.3.1
- 2.3.2Interface
- 2.3.3 Database Schema
- Query Abstract Syntax Tree 2.3.4
- 2.4Implementation
- 2.5Quality Assurance

3

Results and Discussion

- 3.1 Results
- 3.2 Discussion

Conclusion
